

VIA Telematics miles ahead...

Andrei Bulucea

In-vehicle computing: The worst enemies.

- For decades computers have gotten faster, hotter and bigger.
- The MHz race is still going on, pushing power consumption to hundreds of watts.
- Heat dissipation is becoming a real challenge. A Pentium4 dissipates a disturbing 100watts per 100 square mm.
- Size of traditional motherboards is not shrinking due to processor cooling requirements.

Heat: What to do?

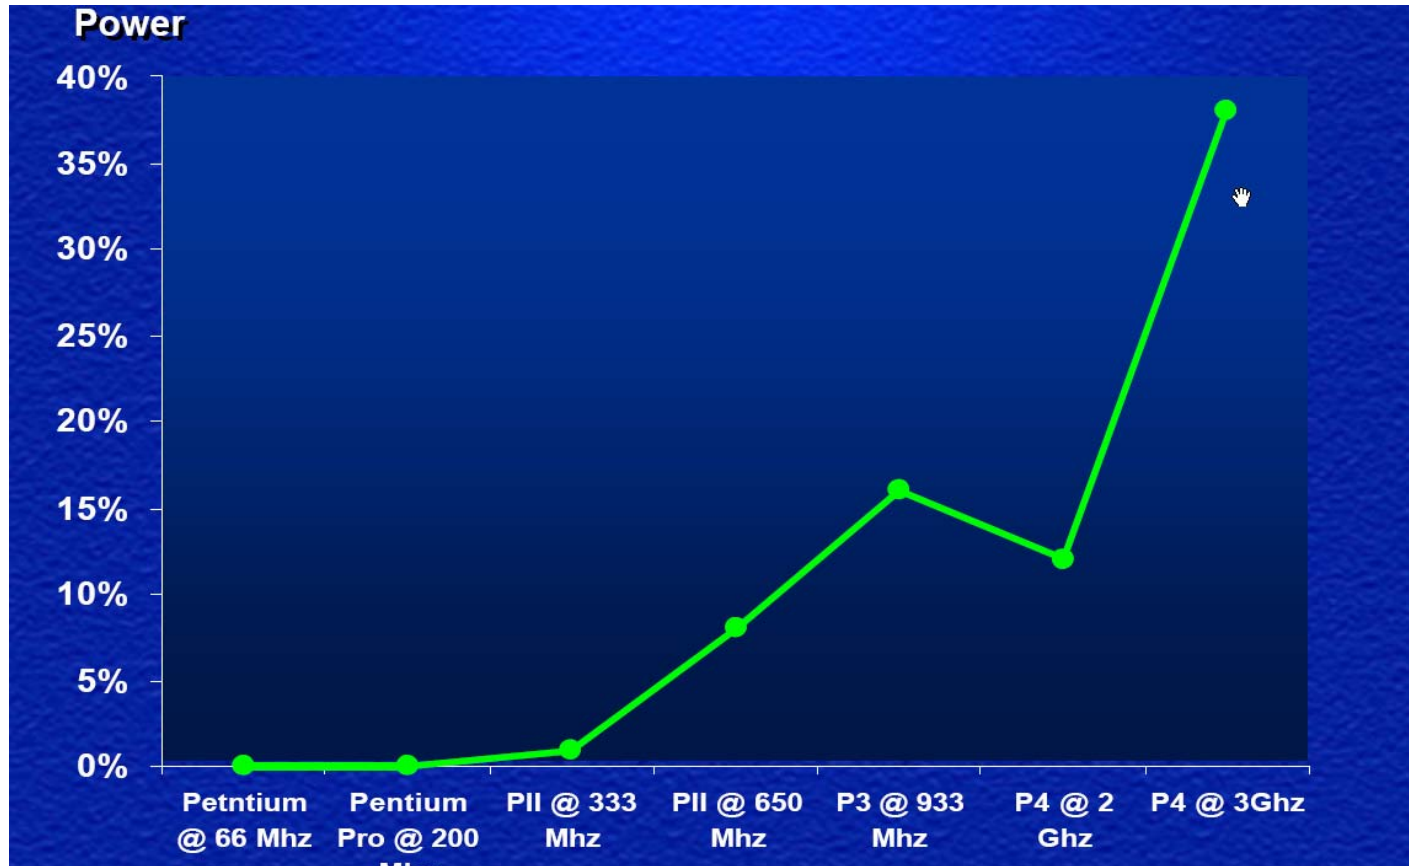

- At the 2002 IEDM conference in San Francisco, Andy Grove quoted Prof Bokor's power density research on current and future processors:
- “Power density – Will get even worse”

Power Density Trends, IEDM 2002

Andy Gove, IEDM 2002

DC Power Leakage, IEDM 2002

Andy Gove, IEDM 2002

Heat Extraction: A real challenge...

- The latest Pentium 4 systems require colossal heat sinks, some water cooled.
- In-vehicle applications require passive heat sinks (no moving parts)

Size: The next frontier...

- In-vehicle applications require small footprint, low power, no moving parts components.
- Mini-ITX, Nano-ITX form factors are the ideal platform small embedded systems.

12V computing using off-the-shelf mini-ITX boards

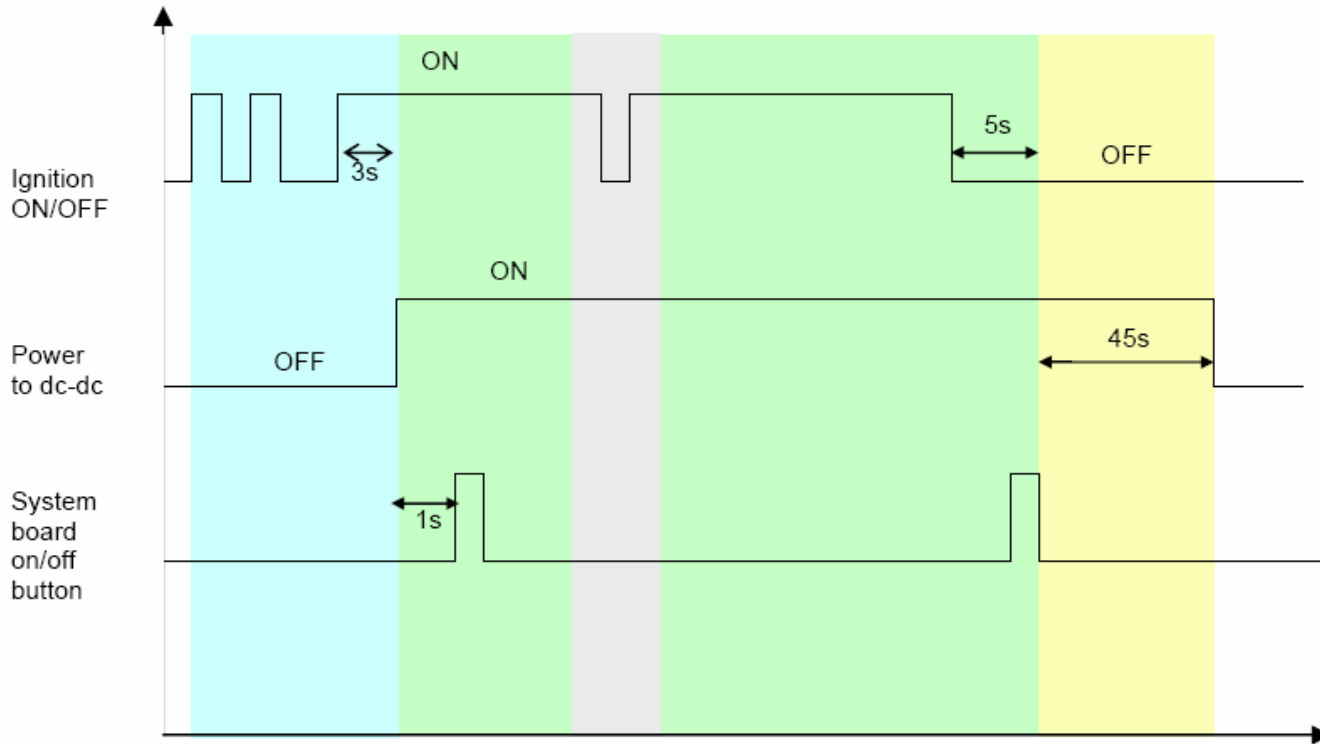

The M-100 is powered using a low power 12V DC_DC converter

- ● ● | Inside the M-100: 12V power

A mini-ITX board next to a 300watt power supply

Power sequencing

Power Sequencing Chart for automotive applications

Turn on sequence

- **Turn-On sequence explained**

- Waits 3 s for battery to reach ~12V
- Provides On/OFF ignition debounce
- Turns on the power to the DC-DC converter, waits for another 1s
- Sends power ON signal for 400ms

Running sequence

- Running Sequence **explained**

- nothing happens, computer is ON

- provides ignition ON/OFF debounce

- waits for an 'key=off' signal

Shutting down

- **Shutting down sequence explained**
 - If ignition=off, then send a 400ms “Off signal” to the motherboard.
 - waits for 45s (OS shutdown sequence) and then cuts Off the power to the DC-DC converter.
 - Based on customer preference, OFF_DELAY and HARD_OFF delay can be changed to any value. For example, the OFF_DELAY can be set to 2 hours and HARD_OFF delay could be set to 24 hours or “0” (forever). Watch for battery drain!

Totals	3.3V	5V	5V SB	12V	Total (watts)
Current (A)	1.64	0.83	0.04	0.06	
Power (W)	5.36	3.49	0.17	0.78	9.80

The Choice: VIA mini-ITX

- Intel P4 or AMD. Too fast, too hot, too big + moving parts. Requires heavy-duty power management.
- National Geode processor. Too slow for multimedia and CPU intensive applications. Price/MHz not appealing.
- VIA-EDEN processor: Cool, nimble and *small*. **Speed='just right'**

Embedded system design cycle

- Board level hardware design and prototyping: ~12months
- Typical costs for in-house board design and prototype: \$500,000
- Cost of prototyping on the VIA Eden platform: About \$100.

The Blessing

- VIA is blurring the line in between the embedded and consumer world:
- Consumers love it
- System designers benefit consumer-scale economics. (low cost processors and boards)

Conclusion

- The VIA EDEN platform is the only platform that allows system integrators to **rapidly design, prototype and produce** systems for a wide variety of Embedded Automotive Applications.
